

Biosintesi e modificazione degli  
antibiotici  $\beta$ -lattamici.

Penicilline e cefalosporine

# Bersagli degli antibiotici e meccanismi di resistenza

# Struttura di alcuni antibiotici $\beta$ -lattamici

Penicillin G

Cephalosporin C

$\beta$ -Lactam antibiotics comprise a  $\beta$ -lactam nucleus coupled to a sidechain. Examples of two penicillins (a) penicillin G and (b) amoxicillin and (c) a cephalosporin, cephadroxil.

# Le penicillin-binding proteins (PBP): enzimi bifunzionali essenziali per la biosintesi del peptidoglicano della parete batterica

# Meccanismo d'azione delle penicilline e delle cefalosporine

La penicillina e la cefalosporina inibiscono la transpeptidasi, l'enzima responsabile della formazione dei legami crociati nella sintesi del peptidoglicano della parete batterica.

La penicillina e la cefalosporina sono **analoghi strutturali** del substrato naturale della transpeptidasi.

**Table 1** Marketed and experimental  $\beta$ -lactam antibiotics. Antibiotics italicized are major commercial antibiotics

Subclass	Marketed $\beta$ -lactam antibiotics
Penicillins	Ampicillin <sup>a</sup> , <i>amoxicillin</i> <sup>a</sup> , bacampicillin, cloxacillin, floxacillin, mezlocillin, nafcillin, oxacillin, penicillin G <sup>a</sup> , penicillin V <sup>a</sup>
Penicillin-resistant penicillins	<i>Methicillin</i> , dicloxacillin
Antipseudomonal penicillins	Carbenicillin, indanyl piperacillin, <i>ticarcillin</i>
First-generation cephalosporins	Cefalothin, cephadrine <sup>a</sup> , cefadroxy <sup>a</sup> , cefazolin, <i>cephalexin</i> <sup>a</sup>
Second-generation cephalosporins	<i>Cefuroxime</i> , <i>cefaclor</i> <sup>a</sup> , cefotetam, cefmetazole, cefonicid
Third-generation cephalosporins	<i>Cefixime</i> <sup>a</sup> , <i>ceftibuten</i> , cefizoxime, ceftriaxone, cefamandol, cefoperazone, cefotaxime, proxetil, <i>cefprozil</i> <sup>a</sup> , ceftazidime, cefuroxime axetil, cefpodoxime
Fourth-generation cephalosporins	<i>Cefepime</i>
Oxycephams	Flomoxef, latamoxef
Cefam	Cefoxitin
Carbapenems	Loracarbef <sup>a</sup> , <i>imipenem</i> , meropenem, panipenem
Monobactams	Aztreonam, carumonam
Clavams ( $\beta$ -lactamase-inhibitors)	<i>Clavulanate</i> , sulbactam, tazobactam
Penicillins/ $\beta$ -lactamase inhibitors	<i>Amoxicillin/clavulanate</i> , ampicillin/sulbactam, piperacillin/tazobactam, <i>ticarcillin/clavulanate</i> , cefoperazone/sulbactam

<sup>a</sup> Orally administered  $\beta$ -lactams

# Biosintesi degli antibiotici $\beta$ -lattamici

Gli antibiotici  $\beta$ -lattamici sono prodotti da funghi (es. *Penicillium* sp. e *Acremonium* sp.).

# Organizzazione modulare della sintetasi peptidica NRPS dell'ACV

Il precursore dell'anello  $\beta$ -lattamico è il tripeptide  
L- $\delta$ - $\alpha$ -aminoadipyl-L-cysteinyl-D-valina prodotto dall'ACV sintetasi.

# Il primo modulo della ACV NRPS

Analisi bioinformatiche hanno identificato un dominio N-terminale atipico simile al lobo C dei domini di condensazione

La delezione di questo dominio abolisce la sintesi di ACV

Il dominio C\* potrebbe essere coinvolto nel reclutamento e/o posizionamento del substrato per la reazione atipica

# Struttura della isopenicillina N sintasi (IPNS) e della deacetossicefalosporina sintasi (DAOCS)

La IPNS e la DAOCS catalizzano le reazioni di chiusura e di espansione degli anelli del nucleo  $\beta$ -lattamico

Struttura della IPNS di *A. nidulans*

Sito attivo dell'enzima

La IPNS è un enzima che utilizza ferro e ossigeno per catalizzare la sintesi dell'anello  $\beta$ -lattamico. L'atomo di ferro nel sito attivo è coordinato da due istidine e un aspartato.

# Meccanismo d'azione proposto per la IPNS

Strutture cristallografiche di IPNS in presenza di substrati che non permettono il completamento della reazione.

**Fig. 2** Overview of the chemistry effected by IPNS. **a** The native substrate of IPNS catalysis (*left*) and a substrate analog that does not undergo a second cyclization (*right*). **b** The crystal structure of the ternary complex of Fe(II)-IPNS-ACV-NO (PDB ID: 1BLZ). The distance between the oxygen atom of NO to the  $\beta$  carbon of cysteine in ACV is 3.3 Å (*black dashes*). **c** The structure of the product of the

in crystallo reaction of Fe(II)-IPNS with ACmC reveals formation of the thiazolidine ring and sulfoxidation of the methylcysteine moiety (PDB ID: 1QJF). **d** A proposed mechanism for catalysis by IPNS. Instead of a formal ET in the second step after substrate binding, the two structures could also be considered resonance forms. For details, see the text

# Meccanismo d'azione proposto per la IPNS

Dalle penicilline alle cefalosporine: espansione dell'anello tiazolidinico ad anello diidrotiazinico catalizzata dalla DAOCS

# Meccanismo d'azione della DAOCS, un enzima ferro- e $\alpha$ -chetoglutarato-dipendente.

Il sito di legame della penicillina è parzialmente sovrapposto a quello dell' $\alpha$ -chetoglutarato  $\rightarrow$  reazione sequenziale

The active site region of DAOCS in complex with substrates and products.

(a) The DAOCS–Fe(II)–2-oxoglutarate complex at 1.5-Å resolution. (b) The DAOCS–Fe(II)–succinate complex at 1.5-Å resolution. (c) The DAOCS–Fe(II)–penicillin G complex at 1.6-Å resolution. (d) The DAOCS–Fe(II)–2-oxoglutarate–penicillin G complex at 1.7 Å resolution. (e) The DAOCS–Fe(II)–2-oxoglutarate–ampicillin complex at 1.5-Å resolution. (f) The DAOCS–Fe(II)–DAOC complex at 1.7-Å resolution. The density next to the penicillin side chain in d,e corresponds to a minor alternative conformation of the side chain. Dioxygen is expected to bind at the position of Wat1 in a. The oxygen of the ferryl iron would be formed at this site. The carbon atoms in 2-oxoglutarate are yellow, in succinate orange, in penicillin G magenta, in ampicillin cyan and in DAOC gold.

# Meccanismo d'azione della DAOCS

- Il legame dell' $\alpha$ -chetoglutarato attiva il Fe permettendo il legame dell' $O_2$
- Con la decarbossilazione ossidativa del co-substrato si forma un intermedio ossidante stabilizzato dal succinato
- Quando la penicillina espelle il succinato scatena l'attacco ossidativo su se stessa
- La formazione di un radicale e il trasferimento di 2 elettroni all'ossigeno producono cefalosporina e  $H_2O$

# Ceppi per la produzione industriale di penicilline

**Table 2** Changes in penicillin manufacturing technology

Fermentation	1950	2000
Carbon source	Lactose	Glucose/sucrose
Operational mode	Batch	Fed-batch
Medium sterilization	Batch	Continuous
Air filtration	Depth filters	Membrane filters
Feeds	None	Many
Morphology	Filamentous	Pelleted
Cycle time	120 h	120–200 h
Tank volume (1,000 gallons)	10–20	20–60
Assay	Bio-assay	HPLC
Control	Temperature only	Computerized
Titer (g/l)	0.5–1.0	>40
Recovery and purification		
Mycelium removal	Filtration	Whole broth
Operational mode	Batch	Semi-continuous
Extraction stages	Many	Single to few
Precursor recovery and re-use	Discarded	Recovered and re-used
Efficiency (%)	70–80	>90
Environmental issues	Few	Many
Bulk cost	~US\$275–350/kg	~US\$15–20/kg

# Produzione di penicilline e cefalosporine

- Ceppi attuali di *Penicillium chrysogenum*: rese fino a circa 70 gr **Penicillina G**/litro di coltura
- Fermentazione aerobica
  - Fonti di carbonio: glucosio e prodotti contenuti nell'acqua di macerazione del mais (corn steep liquor)
  - Fonte di azoto: ammoniaca
  - Aggiunta di acido fenilacetico nella fase stazionaria

# Penicilline semi-sintetiche

- Le penicilline semi-sintetiche si ottengono a partire dalla penicillina G naturale
- Dalla penicillina G viene rimossa la catena laterale producendo acido 6-aminopenicillanico (6-APA)
- Il 6-APA viene acilato con una nuova catena laterale
- Le  $\beta$ -lattam-acilasi sono enzimi in grado di catalizzare queste due reazioni

# Reazioni di idrolisi catalizzate dalle $\beta$ -lattam-acilasi: rimozione della catena laterale acilica

La penicillina acilasi idrolizza la penicillina G ad acido 6-aminopenicillanico (a).

La cefalosporina acilasi idrolizza il glutaril-7-ACA a 7-ACA (b).

Mutanti della cefalosporina acilasi idrolizzano l'adipil-7-ADCA a 7-ADCA (c) e la cefalosporina C a 7-ACA (d).

Il 6-APA e il 7-ACA sono i precursori delle penicilline e delle cefalosporine semi-sintetiche

# Struttura della penicillina acilasi e della cefalosporina acilasi

Struttura della penicillina acilasi di *Escherichia coli*

The crystal structure of *Pseudomonas diminuta* cephalosporin acylase [11]. (Figure drawn with Molscript [27].)

Organismi produttori: batteri e funghi  
(*Escherichia coli*, *Bacillus megaterium*, *Kluyvera citrophila*,  
*Pseudomonas melanogenum*, *Penicillium chrysogenum*).

# Penicillina acilasi

- La penicillina acilasi catalizza l'idrolisi delle penicilline con la formazione dell'acido 6-aminopenicillanico (6-APA), precursore delle penicilline semi-sintetiche.
- La reazione è reversibile e la direzione dipende dal pH.
- Substrati: penicilline, alcune cefalosporine, amidi ed esteri.
- Utilizzata per la produzione di penicilline semi-sintetiche, sia per la produzione di 6-APA che nelle reazioni di sintesi.

Penicillin acylase reaction.

# Penicillina acilasi

- La penicillina acilasi di *E. coli* è formata da due subunità  $\alpha$  (24 kDa) e  $\beta$  (62 kDa) che derivano da un precursore di 95 kDa processato proteoliticamente, con rimozione di un peptide leader di 26 aa che serve a dirigere la proteina nel periplasma e di un peptide interno di 54 aa che dà origine alle subunità e attiva l'enzima.
- La specificità per il substrato (catena laterale della penicillina) si trova nella subunità  $\alpha$ , mentre nella subunità  $\beta$  si trova la serina B1 cataliticamente attiva.

# Meccanismo d'azione della penicillina acilasi

- La serina B1 viene attivata come nucleofilo dal suo stesso gruppo amminico libero.
- Il meccanismo catalitico prevede la formazione di un intermedio covalente acil-enzima.
- L'intermedio acil-enzima viene idrolizzato da una molecola di acqua

# Penicillina acilasi per la produzione di $\beta$ -lattamici semi-sintetici

Sintesi di penicilline semi-sintetiche a partire da **esteri** della catena laterale R (agenti acilanti) e 6-APA.

Sintesi di cefalosporine semi-sintetiche a partire da **esteri** della catena laterale R (agenti acilanti) e 7-ACA/7-ADCA.

# Sintesi dell'amoxicillina

Fig. 1 Scheme of one-pot enzymatic synthesis of amoxicillin in the presence of zinc ions

In presenza di **zinco** l'amoxicillina precipita, favorendo la reazione di sintesi

Fig. 4 Effect of pH on the S/H of the immobilized penicillin acylase. Square: AIPA; circle: KcPA; upright triangle: PCA; diamond: IPA

# Ingegnerizzazione della penicillina acilasi per migliorare la sintesi

Reazioni di **idrolisi** dell'agente acilante o del prodotto della reazione diminuiscono la resa della sintesi

Aumento del rapporto  $V_{\text{synthesis}}/V_{\text{hydrolysis}}$ :  $\beta$  F24 e  $\alpha$  F146

l'enzima deve avere maggiore affinità per l'agente acilante che per l'antibiotico

A (Ampicillin)

B (Ampicillin)

C (Amoxicillin)

D (Amoxicillin)

# Ingegnerizzazione della cefalosporina acilasi

Alterazione della specificità di substrato per migliorare l'idrolisi della cefalosporina C e di adipyl-7-ADCA per la produzione di 7-ACA and 7-ADCA

Mutagenesis alters the substrate specificity of a cephalosporin acylase. The preferred substrate of cephalosporin acylase is glutaryl-7-ACA and activity towards the novel  $\beta$ -lactam fermentation product adipyl-7-ADCA is much lower. Mutants that exhibit an increased catalytic efficiency towards adipyl-7-ADCA were obtained by directed evolution of a cephalosporin acylase. Shown here are the best mutants found by random mutagenesis [17,18\*\*] and saturation mutagenesis of selected residues [20,21]. A greater than 15-fold increase in activity was observed for the single mutant N266M (in single-letter amino acid code). WT, wild type; triple, the multiple mutant M271V/Q291K/T374S.

## Efficient biocatalyst for large-scale synthesis of cephalosporins, obtained by combining immobilization and site-directed mutagenesis of penicillin acylase

Conditions of the first step: pH 8.0, 28°C, 4% (w/v) PGK, 0.03 g/mL immobilized wild Af PGA; Conditions of the second step: initial pH 6.3, 28°C, 150 mM D-PGME, 0.19 g/mL immobilized βF24G mutant Af PGA.

# Resistenza alle penicilline: Meccanismo d'azione delle $\beta$ -lattamasi di classe A

Le  $\beta$ -lattamasi inattivano le penicilline perchè catalizzano l'idrolisi dell'anello  $\beta$ -lattamico.

Le  $\beta$ -lattamasi di classe A appartengono alla famiglia delle serina-idrolasi. **Ser70** è il nucleofilo che attacca l'atomo di carbonio dell'anello  $\beta$ -lattamico. Lys73 attiva Ser70 sottraendo il protone e trasferendolo a Ser130, che a sua volta lo trasferisce all'atomo di azoto dell'anello, aprendolo. Si forma un intermedio acil-enzima che viene deacilato attraverso l'azione di una molecola d'acqua assistita da Glu166.

# Struttura di analoghi dello stato di transizione che agiscono da inibitori delle $\beta$ -lattamasi di classe A

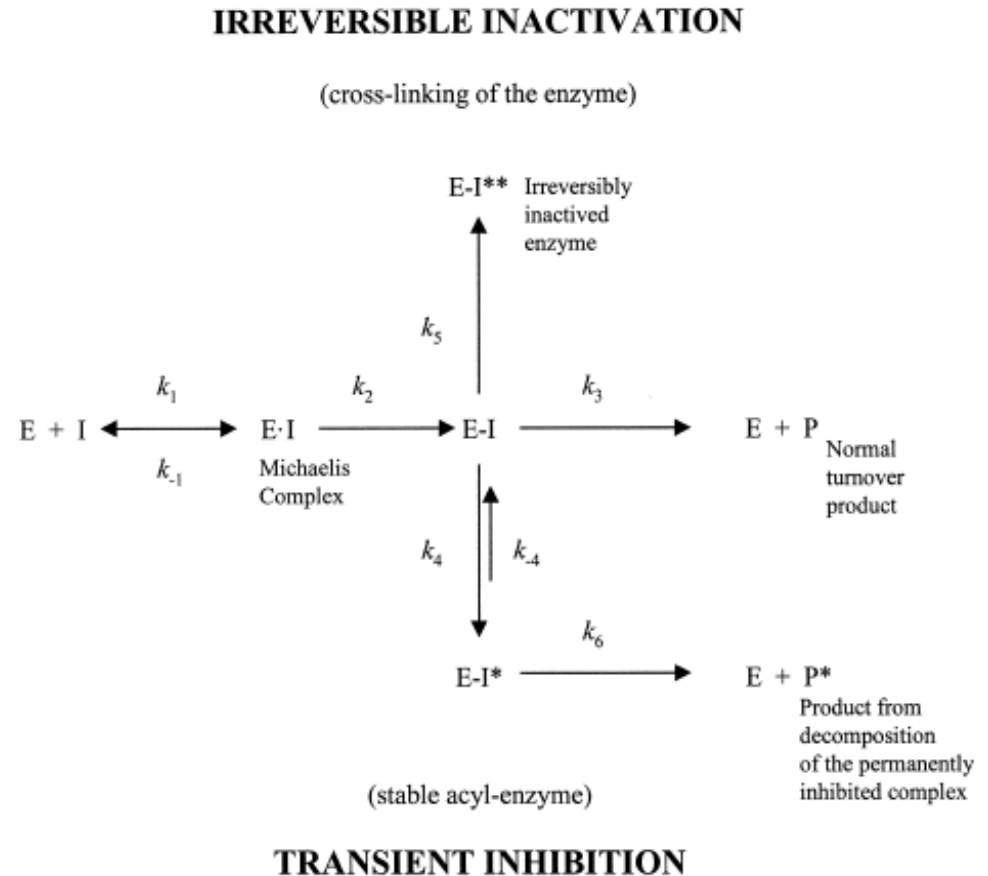

Fig. 1. Structure of  $\beta$ -lactams and transition state analogs with inhibitory activity against serine  $\beta$ -lactamases.

# Schema dell'inattivazione delle $\beta$ -lattamasi

L'intermedio acil-enzima può ripartirsi attraverso due vie, che portano all'inibizione transiente o irreversibile.

In realtà, l'idrolisi dell'intermedio modificato  $E-I^*$  è molto lenta e quindi l'enzima si può considerare permanentemente inibito.

Il cross-linking porta all'inattivazione irreversibile dell'enzima.

# Meccanismo di inattivazione delle $\beta$ -lattamasi di classe A da parte dell'acido clavulanico, un inibitore suicida.

La **sultamicillina**: un farmaco che potenzia l'azione dell'antibiotico (amoxicillina) con quella dell'inibitore delle  $\beta$ -lattamasi (sulbactam)

## Meccanismo d'azione del sulbactam
