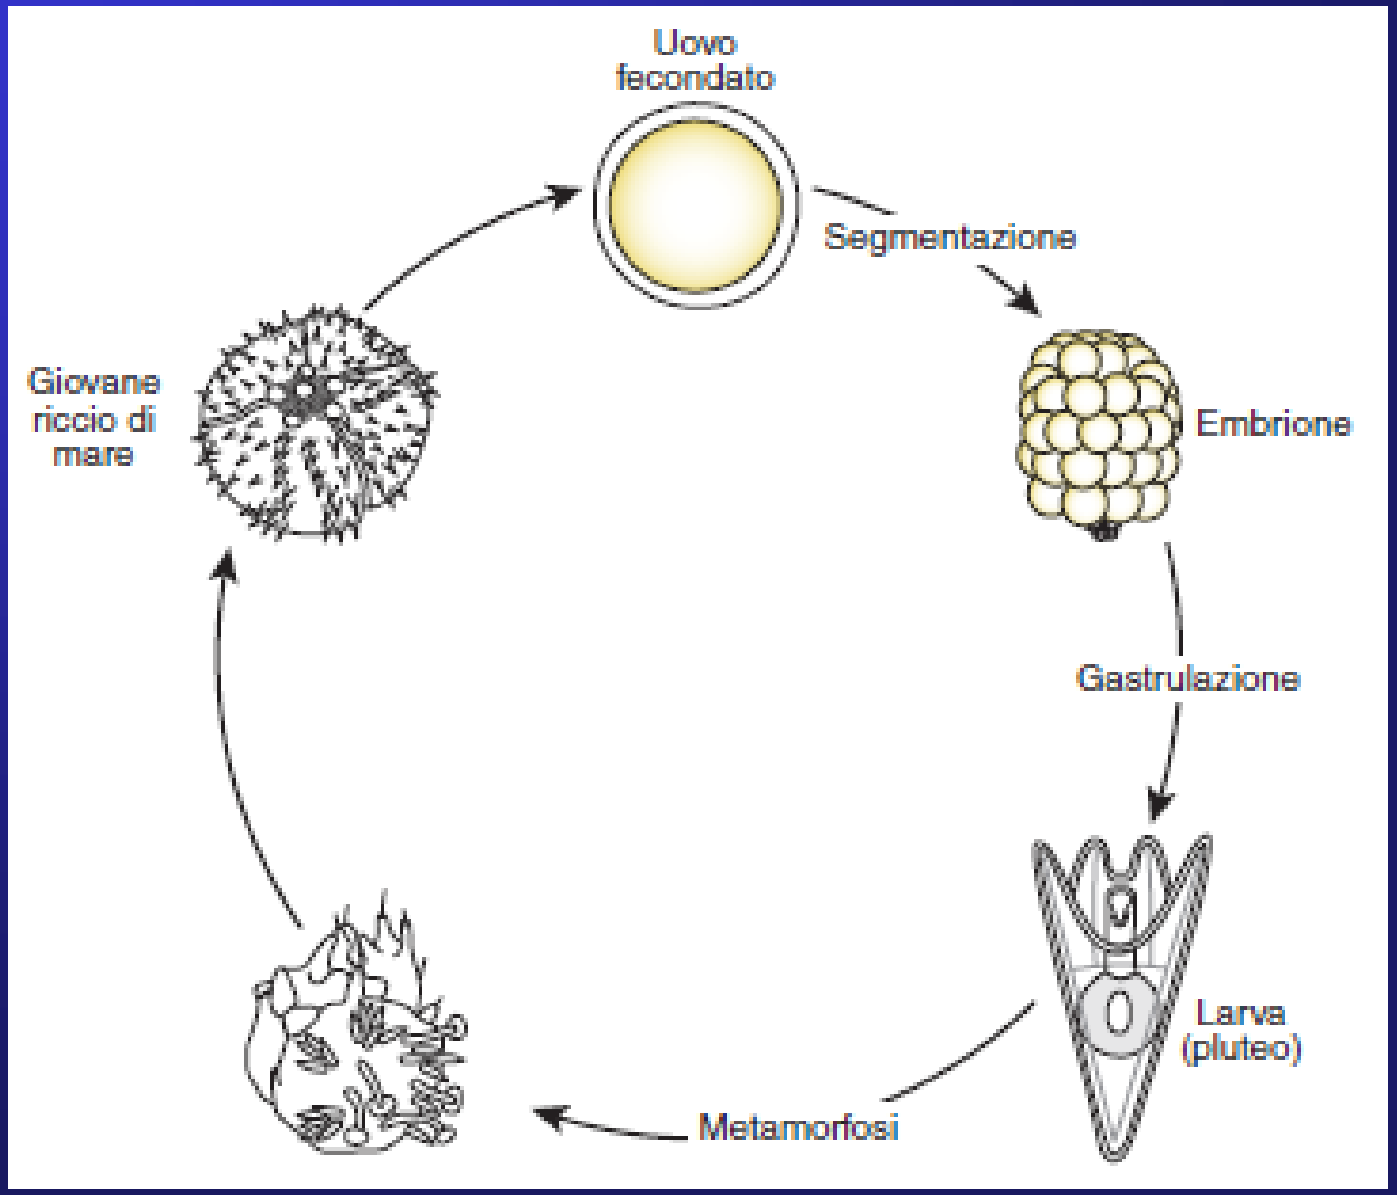
Sviluppo indiretto



L'embrione di riccio di mare presenta degli assi di polarita'

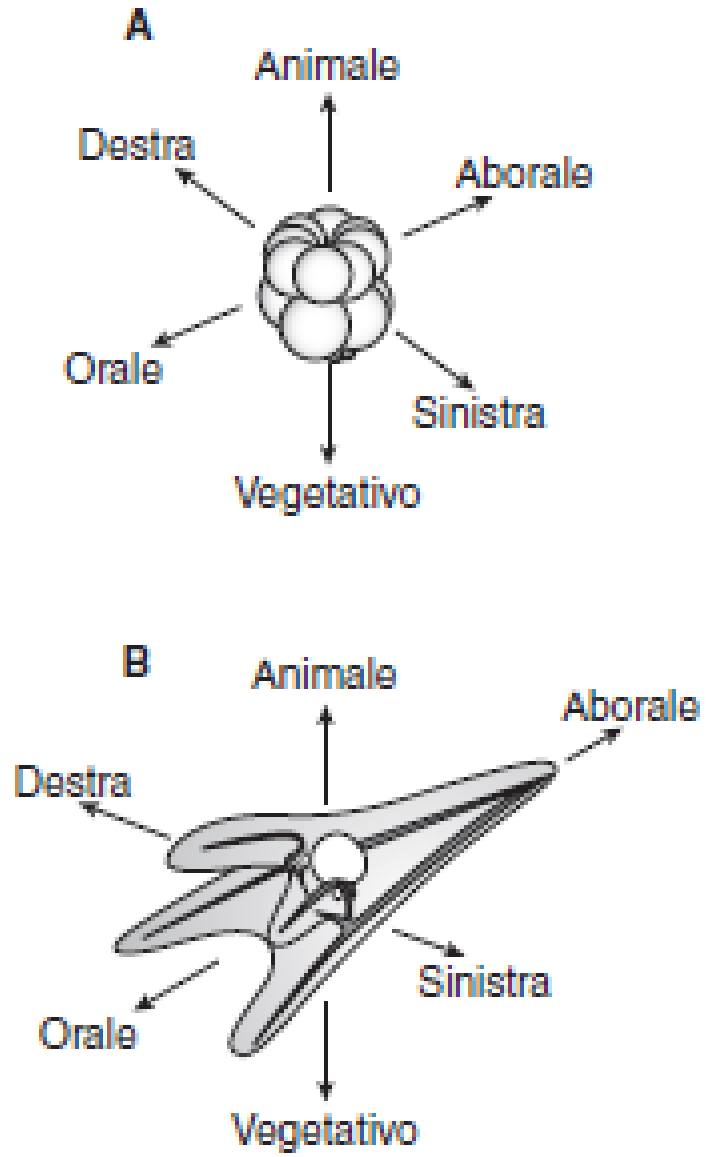


Figura 9

Inoltre, presenta altre caratteristiche che lo rendono un valido organismo modello in biologia dello sviluppo:

sviluppo embrionale esterno

elevato numero di gameti e di embrioni che si possono far sviluppare in modo sincronizzato

tempi brevi di sviluppo (48 ore)

embrione trasparente

facile manipolazione

Formazione blastocele

- Alta affinità tra i blastomeri
- Deposizione di proteoglicani nella cavità blastocelica
- Forza centrifuga che determina il progressivo allontanamento dei blastomeri.

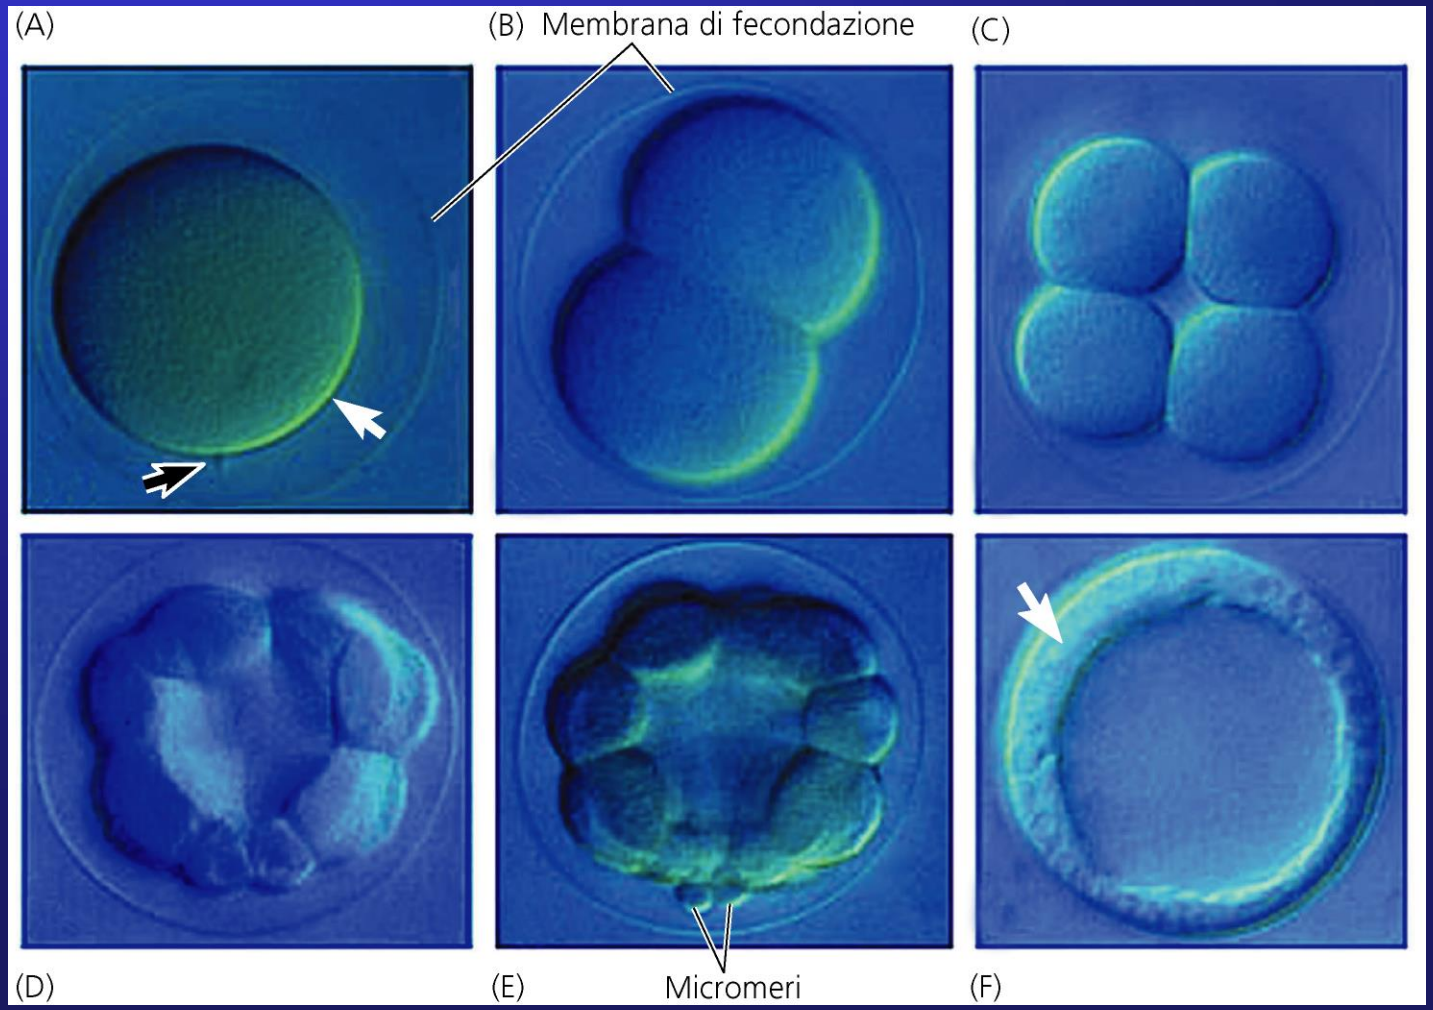

TABLE 1.1 Types of cell movement during gastrulation[a]

Gastrulazione

Type of movement	Description	Illustration	Example
Invagination	Infolding of a sheet (epithelium) of cells, much like the indention of a soft rubber ball when it is poked.		Sea urchin endoderm
Involution	Inward movement of an expanding outer layer so that it spreads over the internal surface of the remaining external cells.		Amphibian mesoderm
Ingression	Migration of individual cells from the surface into the embryo's interior. Individual cells become mesenchymal (i.e., separate from one another) and migrate independently.		Sea urchin mesoderm, *Drosophila* neuroblasts
Delamination	Splitting of one cellular sheet into two more or less parallel sheets. While on a cellular basis it resembles ingression, the result is the formation of a new (additional) epithelial sheet of cells.		Hypoblast formation in birds and mammals
Epiboly	Movement of epithelial sheets (usually ectodermal cells) spreading as a unit (rather than individually) to enclose deeper layers of the embryo. Can occur by cells dividing, by cells changing their shape, or by several layers of cells intercalating into fewer layers; often, all three mechanisms are used.		Ectoderm formation in sea urchins, tunicates, and amphibians

[a] The gastrulation of any particular organism is an ensemble of several of these movements.

DEVELOPMENTAL BIOLOGY 11e, Table 1.1

Ingressione o immigrazione

Ingression — Migration of individual cells from the surface into the embryo's interior. Individual cells become mesenchymal (i.e., separate from one another) and migrate independently.

Sviluppo dell'embrione di riccio di mare. Parte seconda: dalla gastrulazione all'inizio della metamorfosi. La gastrulazione avviene in diverse fasi e produce la cavità interna con cellule dalle quali si originano gli organi interni. La larva risultante è chiamata pluteo. È rappresentato uno solo degli stadi che partono dalla metamorfosi della larva, a simmetria bilaterale, per arrivare al riccio di mare adulto, a simmetria pentaraggiata.
