Introduction: Computational Techniques

In the absence of three-dimensional (3-D) structures of potential drug targets, ligand-based drug design is one of the popular approaches for drug discovery and lead optimization. 3-D structure activity relationships (3-D QSAR) and pharmacophore modeling are the most important and widely used tools in ligandbased drug design that can provide crucial insights into the nature of the interactions between drug target and ligand molecule and provide predictive models suitable for lead compound optimization.

"A pharmacophore is the ensemble of steric and electronic features that is necessary to ensure the optimal supramolecular interactions with a specific biological target and to trigger (or block) its biological response."

C.-G. Wermuth et al., Pure Appl. Chem. 1998, 70: 1129-1143

Introduction to Ligand-Based Drug Design

Chimica Farmaceutica

Definition by IUPAC

A **pharmacophore** is the ensemble of steric and electronic features that is necessary to ensure the optimal supramolecular interactions with a specific biological target structure and to trigger (or to block) its biological response.

A **pharmacophore** does not represent a real molecule or a real association of functional groups, but a purely abstract concept that accounts for the common molecular interaction capacities of a group of compounds towards their target structure.

The **pharmacophore** can be considered as the largest common denominator shared by a set of active molecules. This definition discards a misuse often found in the **medicinal chemistry** literature which consists of naming as **pharmacophores** simple chemical functionalities such as guanidines, sulfonamides or dihydroimidazoles (formerly imidazolines), or typical structural skeletons such as flavones, phenothiazines, prostaglandins or steroids.

Interaction sites used to define a pharmacophore,

- H-bonding,
- hydrophobic
- Electrostatic

Defined by atoms, ring centers and virtual points.

BDZ Cook Model

Modern Pharmacophore Model

QSAR date back to the 19th century

In 1863, A.F.A. Cros at the University of Strasbourg observed that toxicity of alcohols to mammals increased as the water solubility of the alcohols decreased

In the 1890's, Hans Horst Meyer of the University of Marburg and Charles Ernest Overton of the University of Zurich, working independently, noted that the toxicity of organic compounds depended on their lipophilicity.

Louis Hammett (1938) Electronic Parameters (Sigma-Rho) Robert W. Taft (1952) Steric Parameters (Es) Corvin Hansch (1964) Hydrophobic Parameter (LogP - π)

The Hansch Equation

The Hansch Equation

$$\delta_{\mathbf{X}} \log k_i = \delta_{\mathbf{X}} \Delta G_{\text{hydrophobic}} + \delta_{\mathbf{X}} \Delta G_{\text{electronic}} + \delta_{\mathbf{X}} \Delta G_{\text{steric}}$$

Introduction to Ligand-Based Drug Design

The first QSAR equations were based on the observation that partition coefficients, as expressed by log *P* values, are to some extent, correlated to certain biological endpoints.

$$log (1C) = k1 log P + k2\sigma + k3$$

Conc. of compound required to produce a standard response in a given t

Logarithm of the molecule's partition coefficient (1-octanol/water) Hammet Parameter (molecule's electronic characteristics)

$\rho - \sigma - \pi$ Analysis. A Method for the Correlation of Biological Activity and Chemical Structure

By Corwin Hansch and Toshio Fujita¹

Received August 19, 1963

Using the substituent constant, σ , and a substituent constant, π , defined as $\pi = \log P_X - \log P_H (P_H \text{ is the partition coefficient of a parent compound and <math>P_X$ that of a derivative), regression analyses have been made of the effect of substituents on the biological activity of benzoic acids on mosquito larvae, phenols on gram-positive and gram-negative bacteria, phenyl ethyl phosphate insecticides on houseflies, thyroxine derivatives on rodents, diethylaminoethyl benzoates on guinea pigs, and carcinogenic compounds on mice.
